Abstract

We perform a QCD sum rule study of the open-charmed $D_s(2317)$ as a four-quark state. Using the diquark-antidiquark picture for the four-quark state, we consider four possible interpolating fields for $D_s(2317)$, namely, scalar-scalar, pseudoscalar-pseudoscalar, vector-vector, and axial-vector-axial-vector types. We test all four currents by constructing four separate sum rules. The sum rule with the scalar-scalar current gives a stable value for the D_s mass which qualitatively agrees with the experimental value, and the result is not sensitive to the continuum threshold. The vector-vector sum rule also gives a stable result with small sensitivity to the continuum threshold and the extracted mass is somewhat lower than the scalar-scalar current value. On the other hand, the two sum rules in the pseudoscalar and axial-vector channels are found to yield the mass highly sensitive to the continuum threshold, which implies that a four-quark state with the combination of pseudoscalar-pseudoscalar or axial-vector-axial-vector type would be disfavored. These results would indicate that $D_s(2317)$ is a bound state of scalar-diquark and scalar-antidiquark and/or vector-diquark and vector-antidiquark.

I. INTRODUCTION

Recently new resonances with open- and hidden-charmed states have been reported by various experiments. The reported open-charmed states include $D(2308)$ [1], $D_s(2317)$ [2], $D_s(2460)$ [3, 4], and $D_s(2632)$ [5], while $X(3872)$ [6] and $Y(4260)$ [7] have been reported as possible hidden-charmed states. This series of new resonances in charm sector opens a new challenge for heavy quark system and a systematic analysis is required to understand their internal structure and their properties.

Among the open-charmed states, $D_s(2317)$, which is believed to have the quantum number $J^P = 0^+$ [8], is particularly interesting. It might be interpreted as a two-quark state of $c\bar{s}$ [9–12], a four-quark state [13–16], a molecular state of DK [17], or a $D_s(1968)\pi$ atom [18]. The exotic possibility like a four-quark state is quite intriguing as there has been no direct and definitive observation of four-quark states so far.¹ In this picture, $D_s(2317)$ may be considered as a diquark-antidiquark bound state as the diquark picture has been quite useful in describing baryon spectroscopy, static properties, and decay mechanisms. (See Ref. [22] for a general review on the diquark.)

Indeed, Bracco *et al.* [16] recently performed the QCD sum rule calculation of $D_s(2317)$ using the current of scalar-diquark–scalar-antidiquark. Their sum rules give the mass which agrees with the experimental value. This suggests that the $D_s(2317)$ may be regarded as a four-quark state, especially a bound state of scalar-diquark and scalar-antidiquark. However, there can be other possible currents for the diquark-antidiquark system. For example, if the light $[ud]$ diquark is isoscalar, it can have three possible spin quantum numbers: scalar, pseudoscalar, and vector [23, 24]. To form a four-quark state with $J^P = 0^+$ in a simple approach, therefore, one can combine two diquarks with such quantum numbers, which yields three possible choices for the D_s currents, namely, scalar-scalar, pseudoscalar-pseudoscalar, and vector-vector. Since the diquarks in the four-quark state of our concern are isodoublet, other choices like axial-vector–axial-vector combination may not be excluded. In the light quark sector, the axial-vector current gives isovector diquark [24].

Of course, in the constituent quark picture the scalar-diquark may be favored over the pseudoscalar diquark, because in the pseudoscalar channel the upper component of one Dirac spinor is connected only with the lower component of the other spinor. Such combinations should vanish in the nonrelativistic limit. However, QCD sum rules [25] deal with current quarks and the picture based only on the constituent quarks should be carefully examined. In particular, the standard nucleon current [26] involves a linear combination of two types of diquarks, scalar and pseudoscalar, and the both contribute to the nucleon sum rule with a similar weight. Therefore, a further test with the pseudoscalar-pseudoscalar current is required for the D_s sum rule. The other four-quark currents with vector-vector and axial-vector–axial-vector types are interesting as they cannot be ruled out from the constituent quark picture. Thus, dynamical calculations are needed to test these currents, which would be important to understand the possible internal structure of D_s meson when viewed as a tetra-quark state. This will be eventually helpful to investigate the D_s properties in lattice QCD calculations [27].

In this work, we test all the four currents for $D_s(2317)$ in QCD sum rules. For this

¹ The four-quark state picture of the light scalar meson nonet of $(\sigma, \kappa, a_0, f_0)$ and exotic isotensor mesons were discussed, e.g., in Refs. [19, 20]. A possible test for the structure of the light scalar mesons is suggested in Ref. [21].

purpose, we first improve the previous sum rule calculation of Ref. [16] by including higher order terms in the operator product expansion (OPE) that might be non-negligible for sum-rule predictions. We then construct three more sum rules with pseudoscalar-pseudoscalar, vector-vector, and axial-vector-axial-vector currents. By scrutinizing those sum rules, we hope to eliminate certain diquark combinations as the main composition of the tetraquark D_s , which may give a clue for the internal structure of D_s meson.

II. QCD SUM RULES FOR $D_s(2317)$

The quantum numbers of $D_s(2317)$ are believed to be $I(J^P) = 0(0^+)$ [8]. The four-quark current with these quantum numbers can be constructed by combining the diquark $[cu]$ and the antidiquark $[\bar{s}\bar{u}]$. (For the QCD sum rule calculation for the normal $D_s(1968)$ meson, see, e.g., Ref. [28].) The isoscalar diquark in the light (u, d) sector is restricted to the three types: scalar, pseudoscalar, and vector [23, 24]. Thus, its straightforward extension leads to the corresponding three types for $[cu]$ and $[\bar{s}\bar{u}]$. In addition, the axial-vector diquark may be another possibility. By combining the diquark and antidiquark with the same type to make the $J^P = 0^+$ state, we have four possible choices for the four-quark current,

$$J_k = \frac{1}{\sqrt{2}} \left[\epsilon_{ade} \epsilon_{afg} c_d^T \Gamma_k u_e \bar{s}_f \tilde{\Gamma}_k \bar{u}_g^T + (u \rightarrow d) \right], \quad (1)$$

where $k = 1, \dots, 4$ and $\tilde{\Gamma}_k \equiv \gamma^0 \Gamma_k^\dagger \gamma^0$. The color indices are represented by the subscripts and they are chosen so that the diquark in color space belongs to $\bar{\mathbf{3}}_c$ and the antidiquark to $\mathbf{3}_c$. The Dirac matrices between the quarks can be $\Gamma_1 = C$ (pseudoscalar), $\Gamma_2 = C\gamma_5$ (scalar), $\Gamma_3 = C\gamma_5\gamma_\mu$ (vector), and $\Gamma_4 = C\gamma_\mu$ (axial-vector), where C is the charge conjugation operator. For the vector and axial-vector cases, the two vector indices must be contracted to form a scalar state. Note that C , $C\gamma_5\gamma_i$, and $C\gamma_0$ are off-diagonal matrices and therefore they connect the upper and lower components of participating Dirac spinors. The other matrices, $C\gamma_5$, $C\gamma_5\gamma_0$, and $C\gamma_i$ are diagonal so only the upper (or lower) components of the Dirac spinors can be connected to each other. Note that, to form an isoscalar four-quark current, the $(u \rightarrow d)$ term is added in Eq. (1).

In constructing sum rules, we consider the following correlation function,

$$\Pi_k(p) = i \int d^4x e^{ipx} \langle 0 | T[J_k(x) J_k^\dagger(0)] | 0 \rangle. \quad (2)$$

The time-ordering of quark fields is evaluated by the OPE. This OPE is then matched with the hadronic expression of the correlation function via the Borel-weighted sum rule,

$$\int_{m_c^2}^{S_0} dp^2 e^{-p^2/M^2} \frac{1}{\pi} \text{Im} [\Pi^{\text{phen}}(p^2) - \Pi_k^{\text{OPE}}(p^2)] = 0, \quad (3)$$

where M denotes the Borel mass and m_c the charm quark mass. The phenomenological side $\Pi^{\text{phen}}(p^2)$ contains the contribution from the low-lying resonance of our concern as well as higher resonances or multi-meson continuum states. The contributions other than the low-lying resonance have been subtracted according to the QCD duality assumption, which introduces the continuum threshold S_0 . With this relation, we can extract the D_s mass, m_{D_s} , from

$$|\lambda|^2 e^{-m_{D_s}^2/M^2} = \int_{m_c^2}^{S_0} dp^2 e^{-p^2/M^2} \frac{1}{\pi} \text{Im} [\Pi_k^{\text{OPE}}(p^2)], \quad (4)$$

where λ represents the coupling strength of the interpolating field to the physical D_s state. Specifically, we take a derivative with respect to $1/M^2$ and divide the resulting equation by Eq. (4) to get the sum rule for $m_{D_s}^2$. Depending on the interpolating fields characterized by the index k , we can construct four separate sum rules. To get a sensible result, one has to check that the right-hand side of Eq. (4) is positive as constrained by the left-hand side.

The OPE calculation can be done straightforwardly using the same technique developed in Ref. [29]. Namely, we use the momentum-space expression for the charm-quark propagator to keep the charm quark mass finite. For the light-quark part, we calculate in the coordinate-space, which is then Fourier-transformed to the momentum space in the D -dimension. The resulting light-quark part is combined with the charm-quark part before dimensionally regularized at $D = 4$. The OPE for the scalar-scalar correlator Π_2^{OPE} is obtained by summing up the following terms,

$$\begin{aligned}
\frac{1}{\pi} \text{Im}\Pi_2^{\text{pert}} &= -\frac{1}{3 \times 2^{10}\pi^6} \int_0^\Lambda du \left[\frac{3}{2}u(1-u)p^2 - \frac{1}{2}um_c^2 \right] \left(\frac{-L}{1-u} \right)^3, \\
\frac{1}{\pi} \text{Im}\Pi_2^{m_s^2} &= -\frac{m_s^2}{2^7\pi^6} \int_0^\Lambda du \left[-\frac{5}{6}u(1-u)p^2 + \frac{1}{3}um_c^2 \right] \left(\frac{-L}{1-u} \right)^2, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{q}q \rangle} &= \frac{m_c \langle \bar{q}q \rangle}{2^6\pi^4} \int_0^\Lambda du \left(\frac{-L}{1-u} \right)^2 - \frac{m_s \langle \bar{q}q \rangle}{2^5\pi^4} \int_0^\Lambda du [2u(1-u)p^2 - um_c^2] \frac{-L}{1-u}, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{s}s \rangle} &= \frac{m_s \langle \bar{s}s \rangle}{2^6\pi^4} \int_0^\Lambda du [2u(1-u)p^2 - um_c^2] \frac{-L}{1-u}, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle G^2 \rangle}(a, b) &= -\frac{1}{2^9\pi^4} \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle \int_0^\Lambda du \left(1 - \frac{2u}{3} \right) [2u(1-u)p^2 - um_c^2] \frac{-L}{1-u}, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle G^2 \rangle}(c) &= -\frac{m_c^2}{2^{10}3^2\pi^4} \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle \int_0^\Lambda du [3u(1-u)p^2 - 2um_c^2] \left(\frac{u}{1-u} \right)^3, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle G^2 \rangle}(d) &= 0, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{q}Gq \rangle} &= m_c \frac{\langle \bar{q}g_s\sigma Gq \rangle}{2^7\pi^4} \int_0^\Lambda du \frac{u}{1-u} \frac{-L}{1-u}, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{q}D^2q \rangle} &= m_c \frac{\langle \bar{q}D^2q \rangle}{2^5\pi^4} \int_0^\Lambda du \frac{-L}{1-u}, \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{q}q \rangle^2} &= -\frac{\langle \bar{q}q \rangle \langle \bar{s}s \rangle}{12\pi^2} \int_0^\Lambda du [-3u(1-u)p^2 + 2um_c^2], \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{q}q \rangle^3} &= -\frac{1}{9} m_c \langle \bar{q}q \rangle^2 \langle \bar{s}s \rangle \delta(p^2 - m_c^2), \\
\frac{1}{\pi} \text{Im}\Pi_2^{\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle} &= -\frac{1}{48\pi^2} [\langle \bar{s}s \rangle \langle \bar{q}g_s\sigma Gq \rangle + \langle \bar{q}q \rangle \langle \bar{s}g_s\sigma Gs \rangle] \left[\frac{m_c^4}{p^4} + 1 \right]. \tag{5}
\end{aligned}$$

Here $L \equiv u(1-u)p^2 - um_c^2$ and $\Lambda \equiv 1 - m_c^2/p^2$. Compared with the OPE of Ref. [16], the terms containing m_s^2 and $m_s \langle \bar{s}s \rangle$ are new, but we found that their contribution is not important. In addition, we have higher order OPE containing quark condensate like $\langle \bar{q}q \rangle^3$ and $\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle$, which can constitute nontrivial contributions in stabilizing the Borel curves. Using the relation $\langle \bar{q}D^2q \rangle = \langle \bar{q}g_s\sigma Gq \rangle/2$, one can combine the two terms at dimension 5. We

FIG. 1: Diagrams that contribute to the gluon condensate. The solid lines denote quark propagators with specified flavor and the dashed lines are gluons. When the gluon condensate is formed by taking one gluon from one diquark and the other gluon from the other diquark, we have four possibilities. (d) shows one of such possibilities.

have written these terms separately because they are differently related to the corresponding terms in the vector and axial-vector channels. Figure 1 shows the diagrams that contribute to the gluon condensate. In the equations above, we separate the gluon contribution into two terms, one for Figs. 1(a) and (b), and the other for Fig. 1(c). Note that the contribution from Fig. 1(d) vanishes in the scalar-scalar channel but it is non-zero in the vector-vector channel. We did not calculate the diagrams where two gluons emitted from a light quark propagator as they should be parts of the quark condensate.

For the correlators with the other currents, Π_1 (pseudoscalar), Π_3 (vector), and Π_4 (axial-vector), most of the OPE can be obtained from Π_2 by careful inspection. For the pseudoscalar correlator, we find

$$\begin{aligned}
\Pi_1^{\text{pert}} &= \Pi_2^{\text{pert}}, \quad \Pi_1^{m_s^2} = \Pi_2^{m_s^2}, \quad \Pi_1^{\langle \bar{q}q \rangle} = -\Pi_2^{\langle \bar{q}q \rangle}, \\
\Pi_1^{\langle \bar{s}s \rangle} &= \Pi_2^{\langle \bar{s}s \rangle}, \quad \Pi_1^{\langle G^2 \rangle}(a, b) = \Pi_2^{\langle G^2 \rangle}(a, b), \\
\Pi_1^{\langle G^2 \rangle}(c) &= \Pi_2^{\langle G^2 \rangle}(c), \quad \Pi_1^{\langle \bar{q}D^2q \rangle} = -\Pi_2^{\langle \bar{q}D^2q \rangle}, \\
\Pi_1^{\langle \bar{q}Gq \rangle} &= -\Pi_2^{\langle \bar{q}Gq \rangle}, \quad \Pi_1^{\langle \bar{q}q \rangle^2} = -\Pi_2^{\langle \bar{q}q \rangle^2}, \\
\Pi_1^{\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle} &= -\Pi_2^{\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle}, \quad \Pi_1^{\langle \bar{q}q \rangle^3} = \Pi_2^{\langle \bar{q}q \rangle^3},
\end{aligned} \tag{6}$$

while we obtain for vector and axial-vector correlators

$$\begin{aligned}
\Pi_3^{\text{pert}} &= \Pi_4^{\text{pert}} = 4\Pi_2^{\text{pert}}, \quad \Pi_3^{m_s^2} = \Pi_4^{m_s^2} = 4\Pi_2^{m_s^2}, \\
\Pi_3^{\langle \bar{q}q \rangle} &= -\Pi_4^{\langle \bar{q}q \rangle} = 2\Pi_2^{\langle \bar{q}q \rangle}, \quad \Pi_3^{\langle \bar{s}s \rangle} = \Pi_4^{\langle \bar{s}s \rangle} = 4\Pi_2^{\langle \bar{s}s \rangle}, \\
\Pi_3^{\langle G^2 \rangle}(a, b) &= \Pi_4^{\langle G^2 \rangle}(a, b) = 0, \\
\Pi_3^{\langle G^2 \rangle}(c, d) &= \Pi_4^{\langle G^2 \rangle}(c, d) = 2\Pi_2^{\langle G^2 \rangle}(a, b) + 4\Pi_2^{\langle G^2 \rangle}(c), \\
\Pi_3^{\langle \bar{q}D^2q \rangle} &= -\Pi_4^{\langle \bar{q}D^2q \rangle} = 2\Pi_2^{\langle \bar{q}D^2q \rangle}, \\
\Pi_3^{\langle \bar{q}Gq \rangle} &= -\Pi_4^{\langle \bar{q}Gq \rangle} = -\Pi_2^{\langle \bar{q}D^2q \rangle}, \\
\Pi_3^{\langle \bar{q}q \rangle^2} &= -\Pi_4^{\langle \bar{q}q \rangle^2} = 2\Pi_2^{\langle \bar{q}q \rangle^2},
\end{aligned}$$

FIG. 2: (Color online) The Borel curves for the D_s mass in the scalar and pseudoscalar channels. The solid curves are for the Π_2 (scalar) sum rule. The dashed curves are for the Π_1 (pseudoscalar) sum rule. In each case, the thick line is for $\sqrt{S_0} = 2.7$ GeV and the thin line is for $\sqrt{S_0} = 2.4$ GeV. We observe that for the Π_1 sum rule the extracted mass is highly sensitive to the continuum threshold. But for the Π_2 sum rule the Borel curves are stable and not so sensitive to the continuum threshold.

$$\Pi_3^{\langle \bar{q}q \rangle^3} = \Pi_4^{\langle \bar{q}q \rangle^3} = 4\Pi_2^{\langle \bar{q}q \rangle^3}. \quad (7)$$

In the above equations, $\Pi_{3,4}^{(G^2)}$ and $\Pi_{3,4}^{\langle \bar{q}Gq \rangle}$ are calculated directly and their relations to those of the scalar OPE look different from the others. In addition, the $\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle$ term in the vector and axial-vector correlator is not simply related to that of the scalar correlator. Explicitly, it reads

$$\begin{aligned} \frac{1}{\pi} \text{Im} \Pi_3^{\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle} &= -\frac{1}{\pi} \text{Im} \Pi_4^{\langle \bar{q}q \rangle \langle \bar{q}Gq \rangle} \\ &= \frac{1}{96\pi^2} [\langle \bar{s}s \rangle \langle \bar{q}g_s \sigma Gq \rangle + \langle \bar{q}q \rangle \langle \bar{s}g_s \sigma Gs \rangle] \left[\frac{5m_c^4}{p^4} - \frac{3m_c^2}{p^2} + 4 \right]. \end{aligned} \quad (8)$$

III. RESULTS AND DISCUSSION

Given in Fig. 2 are the Borel curves for the mass m_{D_s} in the scalar-scalar and pseudoscalar-pseudoscalar cases. They are obtained by using the following standard values for the QCD parameters as used in Ref. [29],

$$\begin{aligned} \left\langle \frac{\alpha_s}{\pi} G^2 \right\rangle &= (0.33 \text{ GeV})^4, \\ m_c &= 1.26 \text{ GeV}, \quad m_s = 0.15 \text{ GeV}, \\ \langle \bar{q}q \rangle &= -(0.23 \text{ GeV})^3, \quad \langle \bar{s}s \rangle = 0.8 \langle \bar{q}q \rangle, \\ \langle \bar{q}g_s \sigma Gq \rangle &= m_0^2 \langle \bar{q}q \rangle, \quad \langle \bar{s}g_s \sigma Gs \rangle = 0.8 \langle \bar{q}g_s \sigma Gq \rangle. \end{aligned} \quad (9)$$

FIG. 3: (Color online) The Borel curves for the D_s mass in the vector and axial-vector channels. The solid curves are for the Π_3 (vector) sum rule and the dashed curves are for the Π_4 (axial-vector) sum rule. The thick lines are for $\sqrt{S_0} = 2.7$ GeV and the thin lines for $\sqrt{S_0} = 2.4$ GeV.

The parameter m_0^2 denotes the quark virtuality which is normally taken to be 0.8 GeV^2 [30]. To show the sensitivity to the continuum threshold, we vary $\sqrt{S_0}$ from 2.4 GeV (thin lines) to a somewhat larger value, 2.7 GeV (thick lines). The lower bound, 2.4 GeV, is slightly above the KD threshold. The Π_2 sum rule shown by the two solid lines clearly exhibits the Borel stability yielding m_{D_s} around 2.4–2.5 GeV depending on the continuum. The two solid lines (thin and thick lines) are quite close to each other indicating that this sum rule is insensitive to the continuum threshold. Our result is not so sensitive to the uncertainties of the most QCD parameters given above except for the parameter associated with the quark-gluon mixed condensate, m_0^2 . If somewhat lower value $m_0^2 = 0.6 \text{ GeV}^2$ is used in this sum rule, the extracted mass with $\sqrt{S_0} = 2.4$ GeV is found to be around 2.27 GeV. In fact, the quark-gluon mixed condensate plays a crucial role in making the right-hand side of Eq. (4) be positive as constrained by the left-hand side. We found that, without the quark-gluon condensate, this constraint is not satisfied in this particular sum rule. Our stable result may imply that the scalar-scalar current couples strongly to the low-lying pole while its couplings to higher resonances or continuum states are suppressed. Therefore, the scalar-scalar current might be an optimal candidate for the $J^P = 0^+ D_s$ resonance.

On the other hand, the Borel curves for the Π_1 sum rule given by the dashed lines in Fig. 2 show strong sensitivity to the continuum threshold. The thick dashed line ($\sqrt{S_0} = 2.7$ GeV) is substantially different from the thin dashed line ($\sqrt{S_0} = 2.4$ GeV). Also, the strong variation of the curves with respect to the Borel mass clearly shows the Borel instability. From this sum rule, therefore, it is hard to extract any stable value for the D_s mass. In this case, the important contribution coming from the quark-gluon mixed condensate changes its sign from that of Π_2 as can be seen from Eq. (6), which makes the Borel curves unstable. Thus, the quark-gluon mixed condensate contributes differently in the pseudoscalar sum rule. Note that, when $\sqrt{S_0} = 2.4$ GeV, there is no extracted mass for $M \geq 2.82$ GeV as it

FIG. 4: The D_s mass as a function of the charm quark mass m_c with the scalar-scalar (Π_2) current and with the vector-vector (Π_3) current at the Borel mass $M = 2.4$ GeV. The shaded area for Π_2 current is obtained by varying m_0^2 from 0.7 GeV^2 to 0.9 GeV^2 , while that for Π_3 current by varying $\langle \bar{q}q \rangle = -(0.23 \text{ GeV})^3 \sim -(0.25 \text{ GeV})^3$. Other parameters are fixed as given in Eq. (9) in each case with $\sqrt{S_0} = 2.5$ GeV. The dashed line denotes the experimental mass of $D_s(2317)$.

becomes imaginary. One way to understand the success (failure) of the scalar (pseudoscalar) sum rule may be the dominance of the nonrelativistic configuration of the current for the D_s sum rules. Namely, the scalar current survives in the nonrelativistic limit while the pseudoscalar current does not.

Figure 3 shows the results from the Π_3 and Π_4 sum rules. We observe that for the Π_3 sum rule the extracted mass is slightly sensitive to the continuum threshold. As we change $\sqrt{S_0}$ from 2.4 GeV to 2.7 GeV, the extracted mass is in the range of 1.92 to 2.2 GeV, which is somewhat smaller than the experimental D_s mass and the value obtained with the Π_2 sum rule. But the extracted mass can be larger when a slightly larger continuum threshold is used. Furthermore, the Borel curves are quite stable with respect to the Borel mass and thus it can be another possible choice for the D_s current. In the Π_4 sum rule, however, the Borel curves are quite sensitive to the continuum threshold as one can see from the dashed lines in Fig. 3. The result from the Π_4 sum rule with $\sqrt{S_0} = 2.4$ GeV is in fact unphysical since the OPE is found to violate the positivity constraint provided by Eq. (4). Thus, the current with axial-vector-axial-vector composition is ruled out from the possible choices for the D_s current. If this result should be related to the dominance of the nonrelativistic configuration as conjectured in the scalar and pseudoscalar channels, then our results in the vector and axial-vector channels can be understood from the dominance of the time component of diquarks over their spatial components.

As we have discussed above, the obtained masses are mostly dependent of the continuum threshold S_0 . In order to estimate the uncertainties arising from the other parameters we plot the obtained D_s mass as a function of the charm quark mass m_c in Fig. 4. Among the parameters given in Eq. (9), we found that the D_s mass with Π_2 current is most sensitive

to the quark virtuality m_0^2 , while the mass obtained with Π_3 is to the quark condensate $\langle\bar{q}q\rangle$. The shaded area in Fig. 4 are, therefore, obtained with $m_0^2 = 0.7 \text{ GeV}^2 \sim 0.9 \text{ GeV}^2$ for Π_2 and with $\langle\bar{q}q\rangle = -(0.23 \text{ GeV})^3 \sim -(0.25 \text{ GeV})^3$ for Π_3 . As the results are much less sensitive to the other parameters, they are fixed as given in Eq. (9) and $\sqrt{S_0} = 2.5 \text{ GeV}$ is used. Within the range of the parameters considered in this calculation, Fig. 4 shows that the uncertainties are not large and actually they are at the order of 5% for a given continuum threshold $\sqrt{S_0}$.

In summary, we have performed QCD sum rule calculations for $D_s(2317)$ using four different tetra-quark currents with the final quantum numbers $J^P = 0^+$. The sum rule using the scalar-scalar current gives the stable Borel curves with least sensitivity to the continuum threshold. This slightly improves the previous calculation by Bracco *et al.* [16] and supports the picture of $D_s(2317)$ as a bound state of scalar-diquark and scalar-antidiquark. Also the vector-vector sum rule was found to give a stable result for the D_s mass with slightly lower value. This implies that the vector-vector combination could be another possible choice and cannot be simply ruled out for the D_s current. Of course, the possibility that the physical D_s state may be a mixture of the two configurations cannot be excluded. The other two sum rules using the pseudoscalar-pseudoscalar and axial-vector-axial-vector currents yield unstable results with strong sensitivity to the continuum threshold. Therefore, they are unfavored as the main component of the $D_s(2317)$ meson. Although we could not rule out the other models, such as quark-antiquark description,² for the D_s meson by this study, our results indicate the possible four-quark structure with the scalar-scalar and/or vector-vector diquarks of the D_s meson.

² The different expectations from the two-quark and four-quark picture of $D_s(2317)$ in the B meson decays were discussed in Ref. [21].
